1. What is the difference between a model parameter and a prompt parameter?

- **Model parameters** are the learned weights of the model during training (billions of values that determine how the model behaves).
- **Prompt parameters** are runtime settings or instructions, such as the input prompt, temperature, max tokens, or system prompt, which influence how the model responds without changing its learned knowledge.

2. Why would you use a local LLM instead of a cloud API?

- Better privacy because data stays on your computer.
- Works offline after the model is downloaded.
- No per-request API cost.
- Lower latency for local workloads.
- Full control over the model and environment.

3. What is quantisation and how does it affect model quality?

Quantisation reduces the precision of model weights (for example, from 16-bit to 8-bit or 4-bit) to reduce memory usage and speed up inference. The trade-off is that smaller models use fewer resources but may lose a small amount of accuracy or response quality.
